ABSTRACT: This research aims to make buck converter prototype for PLTS system by using fuzzy logic controller. Buck converter is required in the PLTS system if the required unidirectional voltage is smaller than the output voltage of the solar cell. Buck converter used to convert 24 Volt dc voltage to 12 Volt dc with 60 watt capability. While fuzzy logic controller is used to improve buck converter performance based on pulse generation technique for switching. The application of fuzzy logic method is expected to improve the performance of the system by maintaining the stability of buck converter output voltage of 12 volts and reduce the output ripple value. Atmega8535 microcontroller is used to generate PWM pulses for switching on power circuits.

Keywords: Buck converter, fuzzy logic, Atmega8535

1. INTRODUCTION

The solar cell is a semiconductor diode that can convert light into electricity and is a major component in a Solar Power System (PLTS). Electrical energy generated by the PLTS in the form of direct current while the load used by consumers can be alternating and direct current. To convert electrical energy from direct current to alternating current an inverter is used, whereas for converting direct current to another level of current is used dc-dc converter. If the required directional voltage is greater than the output voltage of the solar cell then used dc-dc converter type step up or also known as a boost converter. if the unidirectional voltage required is smaller than the output voltage of the solar cell then used dc converter type step down or also known as buck.

Configuration buck on PLTS system can be used for charging battery system which later can be used as source of inverter to convert to voltage back and forth. In addition, buck configurations are also widely used as drivers for LED lights for lighting systems. In PLTS systems, some of the most important dynamic performance criteria to consider are the ripple, the output voltage, and the recovery time.

Buck converter that many in the market still have a high enough ripple rate which consequently reduces the efficiency so that the extent of waste of electric energy is still happening. Therefore, this research focuses on the design of Buck converter for PLTS system using Atmega8535 microcontroller as pulse generator for switching by using fuzzy logic method. The advantages of this buck configuration are better efficiency, simpler circuit, ripple at lower output voltage so that the filter or filter needed is relatively small.

2. LITERATURE REVIEW

2.1 Buck converter

Buck converter shown in Figure 2.1, the output voltage of the buck converter is always lower than the input voltage. Buck converter consists of one active switch (mosfet) and one passive switch (diode). For low working voltage, the passive switch is often replaced by an active switch so that the shrinkage of power that occurs can be reduced. Both of these switches work alternately. At any time there is only one switch that closes. The average value of the converter output voltage is proportional to the ratio between the time of switching of the active switch to its switching period (work factor) [3][4][5][6]

Fig. 2.1 Topology of buck converter

There are three circuit states:

a. Switch S on, Diode D off;
b. Switch S off, Diode D on;
c. Switch S off, Diode D off.

Switch S is controlled using pulse width modulation (PWM) technique. In this circumstance the sawtooth voltage is compared to the DC voltage. If the sawtooth voltage is lower than the DC voltage then the S switch is closed, otherwise the S switch
will open. When the switch is ON, the dynamic current on the inductor \(i_L(t)\) and the voltage of the capacitor \(V_C(t)\) can be obtained from the following equation:

\[
\begin{align*}
\frac{di_L}{dt} &= \frac{1}{L} (V_{in} - v_o), \quad 0 < t < dT, \quad Q: ON \\
\frac{dv_o}{dt} &= \frac{1}{C} (i_L - V_{in}),
\end{align*}
\]

and when the switch OFF is obtained the following equation;

\[
\begin{align*}
\frac{di_L}{dt} &= \frac{1}{L} (-v_o), \quad dT < t < T, \quad Q: OFF \\
\frac{dv_o}{dt} &= \frac{1}{C} (i_L - v_o),
\end{align*}
\]

The equation of Buck converter function is written in the form;

\[
\hat{v}_{o}(x) = \frac{1}{B} \left[ \frac{1 + R C}{1 + R C + \frac{L}{R + L}} \right] \left[ \frac{L}{R + L} \right] \left[ \frac{R + R C}{R L} \right]
\]

### 2.2 Fuzzy Logic

Fuzzy logic is said to be the old new logic, because the science of modern and methodical fuzzy logic was discovered only a few years ago, when in fact the concept of fuzzy logic itself has been in us for a long time. Fuzzy logic is an appropriate way to map an input space into an output space. The word “Fuzzy” means “vague, vague” and can also mean “fuzzy or impure ideas”. Fuzzy logic takes from the second definition, where it starts from an impure idea, then transforms the idea into something pure. This impurity often occurs in a plant system where disturbances from the environment make its variable inputs uncertain. The basic scheme of fuzzy logic can be seen in Figure 2.2. The fuzzy input is a crisp number (declared) expressed in the input set. [8] [9] [10]

**Fuzzy membership functions there are several kinds:**

a. Triangle membership function

\[
S(x; a, b, c) =
\begin{cases}
0 & \text{for } x < a \\
(x - a)(b - a) & \text{for } a \leq x \leq b \\
(c - x)(c - b) & \text{for } b \leq x \leq c \\
1 & \text{for } x > c
\end{cases}
\]

b. Trapezoidal membership function

\[
S(x; a, b, c, d) =
\begin{cases}
0 & \text{for } x < a \\
(x - a)(b - a) & \text{for } a \leq x \leq b \\
(b - a)(c - b) & \text{for } b \leq x \leq c \\
(c - a)(d - c) & \text{for } c \leq x \leq d \\
1 & \text{for } x > d
\end{cases}
\]
The fuzzy logic control mechanism is shown in Figure 2.5

![Fig. 2.5 The mechanism of the closed loop fuzzy logic control](image)

Fuzzy logic control uses error \( e(k) \) and error change \( \Delta e = e(k) - e(k-1) \). Errors are defined as the difference between the reference and the output measurement values. If the reference voltage and output voltage, then the error voltage can be calculated using the following equation [1] [10] [11]

\[
e(k) = v_{ref} - v_o(k) \\
\Delta e(k) = e(k) - e(k-1)
\]

**Fuzzy inference system**

Fuzzy inference system is part of the conclusion (reasoning) and decision. Knowledge base contains rules. In general fuzzy rules expressed in the form of 'IF-THEN' which is the essence of fuzzy relation, expressed by \( R \), also called fuzzy implications in basic knowledge can be defined as the set of fuzzy implication phases. If -Then rules consist of two main parts, namely:

a. The antecedent part (premise) is the word between if and which is the fuzzy input.

b. The consequent part (conclusion) is the word after then which is the fuzzy output.

Thus fuzzy if then rules is the link between the antecedent (fuzzy input) with the corresponding consequent (output fuzzy). So If then rules can be written with:

IF .............. (antecedent) 
THEN .............. (Consequent)

The basic rules of fuzzy are in a general form:

\[
R: IF x_1 is A_1 AND ..... AND x_n is A_n, THEN y is B
\]

Where \( A_1, \ldots, A_n \) and \( B \) are linguistic values (or fuzzy sets) and \( X_1 \) is \( A_1 \) states that the variable value of \( X_1 \) fuzzy member set \( A_1 \).

**Mamdani Method**

In this model the fuzzy rule is defined as:

IF \( \text{x}_1 \) is \( A_1 \) AND ..... AND \( \text{x}_n \) is \( A_n \), THEN \( y \) is \( B \)

Where \( A_1 \), \ldots, \( A_n \) and \( B \) are linguistic values (or fuzzy sets) and \( X_1 \) is \( A_1 \) states that the variable value of \( X_1 \) fuzzy member set \( A_1 \).

**2.3. Atmega16 Microcontroller**

Microcontroller is a programmable IC repeatedly, either written or deleted. Usually used for automatic and manual controls on electronic devices. AVR Atmega 16 microcontroller has a fairly complete feature. ATmega16 AVR microcontroller has been equipped with internal ADC, internal EEPROM, Timer / Counter, PWM, analog comparator, etc. The features possessed by the ATmega16 microcontroller are as follows [12]:

a. 1/0 channels of 32 pieces, namely port A, port B, port C, and port D.

b. Internal ADC of 8 channels.

c. Three Timer / Counter with benchmarking capability.

d. The CPU consists of 32 registers.

e. SRAM of 512 bytes.

f. Flash memory of 8 kb with Read Write Write capability.

g. SPI interface port

h. EEPROM of 512 bytes that can be programmed during operation.

i. The analog comparator interface.

j. USART port for serial communication.

k. 8-bit microprocessor system based on RISC with a maximum speed of 16 MHz.

l. And others.
From Figure 2.7 can be explained the function of each pin Atmega16 as follows:

a. VCC is a pin that serves as a power supply input.
b. GND embeds the Ground pin.
c. Port A (PortA0 ... PortA7) is a two-way input / output pin and an ADC input pin.
d. Port B (PortB0 ... PortB7) is a two-way input / output pin and a special function pin.

f. Port D (PortD0 ... PortD7) is a two-way input / output pin and a special function pin

g. RESET is the pin that is used to reset the microcontroller.
h. XTAL1 and XTAL2 are external clock input pins.
i. AVCC is the input voltage pin for ADC.
j. AREFF is the input pin of the ADC reference voltage.

3. RESEARCH METHODS

This research activity is planned to produce a prototype of Buck converter with 60 VA capability. Stages of activities undertaken to conduct this research can be described as follows:

Use at most three levels of headings that correspond to chapters, sections and subsections. The first level headings for chapter titles should be in 10pt, bold, justified, and upper case font. Leave one blank line before and after the first level headings, respectively.

3.1 Buck converter simulation

In the early stages of this research, Buck converter simulation was performed with the intention to get a good performance in accordance with the desired prototype.

3.2 Component Selection

The next stage is to select the design components based on simulations that have been done in the early stages. At this stage a list of required components and their specifications will be obtained.

3.3 Purchase of Parts / Equipment

At this stage the purchase of components / equipment required to implement the Buck converter design model with performance according to expected criteria.

3.4. Assembling

At this stage the assembly is based on the tested development model and the selected components. The results to be achieved at this stage is the assembly of Buck converter prototypes

3.5 Testing

In this stage, the feasibility test of the technical results of the assembly. If the test results do not provide the expected performance, then its required the improvement of the design system. The results to be achieved at this stage is the operation of Buck converter prototypes that can optimize the use of solar energy

3.6 Reporting

At this stage conducted reporting of research results. Reporting of results is made in the form of a report book

4. RESULTS AND DISCUSSION

4.1 Buck Converter Simulation

Before making a prototype buck converter with 60A capability, then first do the design and simulate it. This simulation result is needed to see the characteristics of this type of converter buck

Fuzzy logic control uses error e (k) and error change \( \Delta e = e (k) - e (k-1) \). Errors are defined as the difference between the reference and the output measurement values

3.2 Buck Hardware Converter generated

The following figure shows the hardware of the completed buck converter
3.3 Buck Converter Testing

Figure 4.10 shows the slow system response to the steady state state, although there is no ripple, because the load is too small.

Figure 4.11 shows the rapid response of the system to the steady state, although there is a ripple, but it does not result in overshoot. From the picture also seen the output voltage generated is 12.4 VDC.

5. CONCLUSION

The converted buck converter has 24 VDC input with 12 VDC output capability of 60 VA maximum.

Testing a buck converter using a 100 Ohm 5 watt load shows a fairly good response with an output voltage of 12.4 VDC.

This Buck Converter circuit can be used for PLTS system with maximum ability of 60 VA
